Step 1: Explore Confidentiality

Objective: Understand how confidentiality is maintained and identify security violations when unauthorized access occurs.

1. Create a File Containing Sensitive Information

- Open a terminal or command prompt.
- Create a text file named sensitive_file.txt:
  Linux:
  echo "Confidential Data: Usernames and Passwords" > sensitive_file.txt
  Windows:
  Open Notepad, type Confidential Data: Usernames and Passwords, and save the file as sensitive_file.txt.

2. Restrict File Permissions

- Set file permissions so only the owner can access it:
  Linux:
  chmod 600 sensitive_file.txt
  Explanation: The 600 permission allows the owner to read/write the file but denies access to others.
  Windows:
  Right-click the file → Properties → Security → Edit permissions → Deny access for all users except the owner.

3. Simulate Unauthorized Access

- Switch to another user or simulate unauthorized access:
  Linux:
  su - otheruser
  cat sensitive_file.txt
  Windows:
  Switch user accounts or create a new user, then try opening the file.
- Observation:
  Expected error message: "Permission denied"
- Discussion:
  How this protects confidentiality.
  Real-world examples, such as protecting medical or financial records.

Step 2: Analyze Integrity

Objective: Understand how data integrity can be compromised and verify its integrity using
hashing.

1. Create or Access a Log File

   Use an existing log file or create a simulated one:
   Linux: sudo nano /var/log/syslog (requires root access).
   Windows: Open Event Viewer (eventvwr) or create a text file named 19logfile.txt.

2. Modify the Log File (Simulate Unauthorized Changes)

   Add or change log entries to simulate a security violation:
   Linux: Edit the file: sudo nano /var/log/syslog → Add a fake entry:
   Jan 1 12:00:00 UnauthorizedAccess: Admin login.
   Windows: Open logfile.txt in Notepad and add UnauthorizedAccess: Admin login.

3. Verify Integrity with Hashing

   Calculate the file's hash before and after modification:
   Linux: Use sha256sum logfile.txt and note the hash.
   Windows: Use PowerShell: Get-FileHash .\logfile.txt -Algorithm SHA256

Observe the hash difference.
Discussion: Discuss how unauthorized changes compromise data integrity. Relate this to tampering scenarios in real-world applications, such as altering financial records or audit logs.

```
  GNU nano 6.2                                                    /var/log/syslog *

```
atharv@atharv:~/Documents/IS$ sudo nano /var/log/syslog
atharv@atharv:~/Documents/IS$ ls
sensitive_file.txt
atharv@atharv:~/Documents/IS$ sha256sum /var/log/syslog
a126b2b6740a4c8e7b385246ebcdb129a9d5bcde1571f533dfc12b1e71e44c00  /var/log/syslog
atharv@atharv:~/Documents/IS$
```

Step 3: Examine Availability
Objective: Explore how system availability is affected during an attack or resource overload.

1. Set Up a Simple Web Server (Optional)
Linux: Use Python to start a basic web server: python3 -m http.server 8080
Windows: Use IIS or WAMP/XAMPP to set up a local server.

2. Simulate Denial-of-Service (DoS) Attack
Use a tool to overload the server with requests:
Linux: Install and use ab (Apache Benchmark):
ab -n 1000 -c 100 http://localhost:8080/
-n: Total number of requests.
-c: Number of concurrent requests.
Windows: Use a custom PowerShell script or any load-testing tool like JMeter.

3. Monitor Server Behavior
Observe the server response time during the attack:
Linux: Check server logs or terminal output for delays or errors.
Windows: Use Task Manager or Resource Monitor to track CPU and network usage.
Note any timeouts or connection refusals.
204. Restore Normal Operations
Stop the attack and ensure normal availability:
Linux: Terminate the ab command or server process (Ctrl+C).
Windows: Stop the server or restart it via IIS Manager.
Verify that the server is responsive again.

5. Discussion
Relate this to real-world examples of denial-of-service attacks on popular websites or applications. Discuss strategies to mitigate such attacks, such as rate-limiting, firewalls, or load balancers.

Step 4: Document Observations

a. For each step, document:

- Actions performed.
- Observations (e.g., error messages, response times).
- Screenshots of commands and results.

b. Analyze how each violation impacts the overall security of the system.
